

## ABSTRACT

An apparatus enabling automatic determination of a portion that reliably represents a feature of a speech waveform includes: an  
5 acoustic/prosodic analysis unit (92) calculating, from data, distribution of an energy of a prescribed frequency range of the speech waveform on a time axis, and for extracting, among various syllables of the speech waveform, a range that is generated stably, based on the distribution and the pitch of the speech waveform; cepstral analysis unit (94) estimating, based on the  
10 spectral distribution of the speech waveform on the time axis, a range of the speech waveform of which change is well controlled by a speaker; and a pseudo-syllabic center extracting unit (96) extracting, as a portion of high reliability of the speech waveform, that range which has been estimated to be the stably generated range and of which change is estimated to be well  
15 controlled by the speaker.
